

the API calls **724** provided by the mobile operating system such as operating system **714** to facilitate functionality described herein.

The applications **720** may use built-in operating system functions (e.g., kernel **728**, services **730** and/or drivers **732**), libraries **716**, or frameworks/middleware **718** to create user interfaces to interact with users of the system. Alternatively, or additionally, in some systems, interactions with a user may occur through a presentation layer, such as the presentation layer **744**. In these systems, the application/module “logic” can be separated from the aspects of the application/module that interact with a user.

Some software architectures use virtual machines. In the example of FIG. **8**, this is illustrated by a virtual machine **748**. The virtual machine **748** creates a software environment where applications/modules can execute as if they were executing on a hardware machine (such as the machine **800** of FIG. **9**, for example). The virtual machine **748** is hosted by a host operating system (e.g., operating system **714**) and typically, although not always, has a virtual machine monitor **746**, which manages the operation of the virtual machine **748** as well as the interface with the host operating system (i.e., operating system **714**). A software architecture executes within the virtual machine **748** such as an operating system (OS) **750**, libraries **752**, frameworks **754**, applications **756**, and/or a presentation layer **758**. These layers of software architecture executing within the virtual machine **748** can be the same as corresponding layers previously described or may be different.

FIG. **9** is a block diagram illustrating components of a machine **800**, according to some example embodiments, configured to read instructions from a machine-readable medium (e.g., a machine-readable storage medium) and perform any one or more of the methodologies discussed herein. In some embodiments, the machine **800** is similar to the ECS device **101**. Specifically, FIG. **9** shows a diagrammatic representation of the machine **800** in the example form of a computer system, within which instructions **816** (e.g., software, a program, an application, an applet, an app, or other executable code) for causing the machine **800** to perform any one or more of the methodologies discussed herein may be executed. As such, the instructions **816** may be used to implement modules or components described herein. The instructions transform the general, non-programmed machine into a particular machine programmed to carry out the described and illustrated functions in the manner described. In alternative embodiments, the machine **800** operates as standalone device or may be coupled (e.g., networked) to other machines. In a networked deployment, the machine **800** may operate in the capacity of a server machine or a client machine in a server-client network environment, or as a peer machine in a peer-to-peer (or distributed) network environment. The machine **800** may comprise, but not be limited to, a server computer, a client computer, a personal computer (PC), a tablet computer, a laptop computer, a netbook, a set-top box (STB), a personal digital assistant (PDA), an entertainment media system, a cellular telephone, a smart phone, a mobile device, a wearable device (e.g., a smart watch), a smart home device (e.g., a smart appliance), other smart devices, a web a network router, a network switch, a network bridge, or any machine capable of executing the instructions **816**, sequentially or otherwise, that specify actions to be taken by the machine **800**. Further, while only a single machine **800** is illustrated, the term “machine” shall also be taken to include a collection

of machines that individually or jointly execute the instructions **816** to perform any one or more of the methodologies discussed herein.

The machine **800** may include processors **810**, memory **830**, and input/output (I/O) components **850**, which may be configured to communicate with each other such as via a bus **802**. In an example embodiment, the processors **810** (e.g., a Central Processing Unit (CPU), a Reduced Instruction Set Computing (RISC) processor, a Complex Instruction Set Computing (CISC) processor, a Graphics Processing Unit (GPU), a Digital Signal Processor (DSP), an Application Specific Integrated Circuit (ASIC), a Radio-Frequency Integrated Circuit (RFIC), another processor, or any suitable combination thereof) may include, for example, a processor **812** and a processor **814** that may execute the instructions **816**. The term “processor” is intended to include multi-core processor that may comprise two or more independent processors (sometimes referred to as “cores”) that may execute instructions contemporaneously. Although FIG. **9** shows multiple processors, the machine **800** may include a single processor with a single core, a single processor with multiple cores (e.g., a multi-core processor), multiple processors with a single core, multiple processors with multiple cores, or any combination thereof.

The memory/storage **830** may include a memory, such as a main memory **832**, a static memory **834**, or other memory, and a storage unit **836**, both accessible to the processors **810** such as via the bus **802**. The storage unit **836** and memory **832**, **834** store the instructions **816** embodying any one or more of the methodologies or functions described herein. The instructions **816** may also reside, completely or partially, within the memory **832**, **834**, within the storage unit **836**, within at least one of the processors **810** (e.g., within the processor’s cache memory), or any suitable combination thereof, during execution thereof by the machine **800**. Accordingly, the memory **832**, **834**, the storage unit **836**, and the memory of processors **810** are examples of machine-readable media **838**.

As used herein, “machine-readable medium” means a device able to store instructions and data temporarily or permanently and may include, but is not limited to, random-access memory (RAM), read-only memory (ROM), buffer memory, flash memory, optical media, magnetic media, cache memory, other types of storage (e.g., Erasable Programmable Read-Only Memory (EEPROM) and/or any suitable combination thereof. The term “machine-readable medium” should be taken to include a single medium or multiple media (e.g., a centralized or distributed database, or associated caches and servers) able to store the instructions **816**. The term “machine-readable medium” shall also be taken to include any medium, or combination of multiple media, that is capable of storing instructions (e.g., instructions **816**) for execution by a machine (e.g., machine **800**), such that the instructions, when executed by one or more processors of the machine **800** (e.g., processors **810**), cause the machine **800** to perform any one or more of the methodologies described herein. Accordingly, a “machine-readable medium” refers to a single storage apparatus or device, as well as “cloud-based” storage systems or storage networks that include multiple storage apparatus or devices. The term “machine-readable medium” excludes signals per se.

The input/output (I/O) components **850** may include a wide variety of components to receive input, provide output, produce output, transmit information, exchange information, capture measurements, and so on. The specific input/output (I/O) components **850** that are included in a particular
